Interaction adjustment and personal development:
Adult third culture kids and mono-culture kids

Abstract

Purpose – The aim of this study is to explore the relationship between interaction adjustment and personal development for expatriates and to examine whether this differs between adults that have, and have not, lived abroad during their adolescence.

Design/methodology/approach – We use survey responses from 424 business expatriates in Asia distinguishing between adult third culture kids (ATCKs) that have lived abroad during their adolescence and adult mono-culture kids (AMCKs) that have not.

Findings – Our results show that while interaction adjustment generally improves the experience of personal development, this effect is stronger for ATCKs. AMCKs will experience personal development almost independently of their interaction adjustment with host nationals solely due to the novelty of the international experience. For ATCKs, just being in the new country is not enough for them to feel they have developed personally; they need to engage more deeply with the local population to achieve this.

Originality/value – The study contributes to the literature that links international experience to adjustment and to the literature that connects adjustment to personal development. By combining the two literatures, we provide new knowledge that explains in greater detail how adjustment is linked to personal development.

Introduction

The emergence of new types of careers in global organizational contexts means that personal development has become central for individuals (Banai and Harry, 2004; Baluku et al., 2018; Baruch and Rousseau, 2019; Mutter and Thorn, 2019; Redondo, Sparrow and Hernández-Lechuga, forthcoming). This notion suggests that managers value expatriation for the opportunity it brings for personal development, despite that such personal development may not help them advance within their employing organization (Stahl, Miller and Tung, 2002). As such, the international experience has been shown to hold high intrinsic value and can be used by individuals as an asset to further their personal development (Doherty, Dickmann and Mills, 2011; Lauring, Selmer and Jacobsen, 2014; Quer, Rienda, Andreu and Miao, 2019). Many expatriates cite as their reasons for accepting international assignments not their desire to achieve project results, to be good corporate citizens, or to advance their company careers, but their personal development (Inkson, Arthur,
Pringle and Barry, 1997). Dickman, Doherty, Mills and Brewster (2008) dismissed financial rewards as being the primary source for relocation motivation; instead, development and career considerations impacted the decision the most. Similar results were found by Thorn (2009) and McNulty, De Cieri and Hutchings (2013). Although the cross-cultural context is particularly fertile ground for personal development and transformation, not all expatriates take advantage of the opportunity for their own personal growth.

It has been proposed that expatriates that have developed personally during their time abroad have the potential to become especially competent as global leaders and are therefore valuable to companies with global operations (Lam and Selmer, 2004). In this regard, Scullion and Collings (2006) noted that multinational corporations (MNCs) are facing critical challenges in attracting, retaining, and developing the necessary managerial talent for their global operations. One group that has received some attention in relation to global talent management is adult third culture kids (ATCKs). These are individuals with extended experience of living in a foreign country during their adolescence (Moore and Barker, 2012). Tarique and Weisbord (2013) predict that persons acquiring intercultural experience during their childhood are better able to adjust to new cultural settings. Selmer and Lauring (2014) found that ATCKs had a higher extent of general adjustment (but not interaction or job adjustment) than adults with no significant intercultural experiences during their childhood. The above makes it relevant to link expatriate adjustment to personal development because earlier studies have demonstrated personal development as a positive outcome from having acquired international experience before becoming an adult (cf. Lam and Selmer, 2004; Haslberger, Brewster and Hippler, 2013).

In this study, we explore the effect of ATCK status on the relationship between interaction adjustment and (experienced) personal development during a relocation abroad for work. We focus on interaction adjustment that includes socializing and interacting day-to-day with host nationals because this is where ATCK status could have a particularly strong impact (cf. Waxin, 2004). The assumption is that ATCKs are more sensitive and competent dealing with other cultures and that they adjust better, compared to AMCKs, because of their early international experiences (see Selmer, McNulty and Lauring, forthcoming). Empirical research has not, however, proven the accuracy of this statement. While a number of studies have assessed the specific qualities of TCKs and ATCKs (Dewaele and van Oudenhoven, 2009; Lyttle, Barker and Cornwell, 2011; Melles and Schwartz, 2013), and others have directly compared ATCKs with AMCKs (Selmer and Lauring,
2014; Abe, 2018), few (if any) studies have yet explored ATCK status as a boundary condition for
the role of adjustment in relation to experienced personal development. In this study, we aim to
examine if ATCKs and AMCKs experience interaction adjustment in the same way and the extent
to which it impacts on personal development.

Our research provides a relevant and novel contribution to the developing literature that links
global talent management to individuals’ personal characteristics, which few studies have (so far)
exploded empirically (Lauring, Selmer and Kubovcikova, forthcoming). This brings value for work
organizations in terms of what types of individuals they would want to recruit, develop and retain.
Few prior studies have focused on differential effects of adjustment between expatriates with and
without significant intercultural experiences during their childhood; that is, between ATCKs and
AMCKs. As such, our findings contribute to the ongoing discussion about the relationship between
international experience and expatriate adjustment (Froese and Peltokorpi, 2013; Takeuchi and
Chen, 2013). In addition, we provide new insights for understanding the mechanisms linking
expatriate adjustment and personal development that have so far received little empirical attention
(Haslberger et al., 2013).

Background

In general, scholars seem to agree that developmental learning experiences gained through
interactions with the foreign location in various situations influence expatriate adjustment and thus
expatriate success (Caligiuri and Tarique, 2012). The earlier these experiences are introduced to
and experienced by the individual, the longer-lasting and deeper the learning and impact are likely
to be (Tarique and Weisbord, 2013). Hence, the experience obtained in a foreign culture may
trigger ‘personal development’, defined in a work context as a purposeful, specifiable and
structured activity, which seeks to develop discrete skills or qualities, whose effects can either be
‘positive’, ‘negative’ or ‘transitory’ (Irving and Williams, 1999). Others define personal
development as having an improved awareness and identity, and the development of talent and
potential that enhances the quality of life and contributes to the realization of dreams and
aspirations (Aubrey, 2010).

Personal development in an international context has been examined most often in the study
broad literature. Kauffman and Kuh (1984) determined that a study abroad experience was
associated with changes in selected aspects of personal development for those that went abroad

http://mc.manuscriptcentral.com/ccsm
but not for those that stayed behind. Using the challenge-response theory (Sanford, 1967), they
argued that college students’ development occurred in response to novel situations and ideas,
which were difficult to assimilate given an individual’s current worldview. Personal development
arises from the realization that previously learned responses become non-functional in a foreign
setting and that to retain ‘situational mastery’ (Kauffman & Kuh, 1984, p. 2), the individual must
learn to develop new response mechanisms. Early research suggests that, for overseas students,
outcomes related to personal development includes increased self-confidence, enhanced
interpersonal communication, an increased capacity for critical thinking, and greater tolerance for
ambiguity (McGuigan, 1958; Nash, 1976; Hensley and Sel, 1979; Pyle, 1981; Baker, Perkins and
Comber, 2014). However, Gullahorn and Gullahorn (1966) found in their study of 400 US college
students and over 5,000 scholarship grantees that not all outcomes are positive: participants that
reported more extensive interaction with host country nationals (HCNs) and greater personal
development and satisfaction were also less settled and less committed to their professional goals,
whereas those that furthered only their professional (but not personal) development were older and
more focused on integrating their experience into future job opportunities (see also Nadeem and
Mumtaz, 2018).

In this study, the argument by Haslberger, Brewster and Hippler (2013) that personal
development can be considered as an adjustment outcome is central to our explorations. We focus
in particular on interaction adjustment because it is strongly related to a deeper involvement with
local individuals at work or outside of it (cf. Mahajan and Toh, 2014; Chen and Shaffer, 2018;
Gudmundsdottir et al., 2019). For example, interaction adjustment has been found to correlate with
a large social network (Claus, Maletz, Casoinic and Pierson, 2015). Compared to experiences that
do not involve communication, it has been argued that interaction with dissimilar others is a more
central source for personal development (Rogoff, 1990).

Hypotheses

Interaction adjustment and personal development
For decades, personal development has been connected to international experience (e.g. Gullahorn
and Gullahorn, 1966). Inkson and Myers (2003) describe how a large number of Australians and
New Zealanders make a tour to Europe as their great ‘overseas experience’, which is defined by
significant personal development. They argue that the greater the cultural extension and

http://mc.manuscriptcentral.com/ccsm
uncertainty of overseas experience, the greater the potential for personal development of the
individual, suggesting that intercultural experience and interaction with host nationals can result
in positive personal development (Mendenhall, Kuhlmann, Stahl and Osland, 2002). In relation to
adjustment, Nicholson (1984) defines work role transitions as a change in job content and argues
that such transitions could have a profound impact on the future development of individuals, if not
also their organizations. Personal change and the development involved is absorbed through the
person altering his or her frame of reference, values, or other identity-related attributes in
interactions with locals (Lauring, 2008). In this way adjustment, and in particular interaction
adjustment, becomes an important aspect of personal development (Brandstädter, 2009). Based
on the above, we argue that international experiences and the intercultural adjustment involved
may lead to feelings of personal development among expatriates.

Hypothesis 1. There is a positive association between interaction adjustment and
experienced personal development.

The effect of being an ATCK
TCKs have been found to possess distinct personal characteristics in terms of flexibility,
international awareness and cross-cultural experience (Cockburn, 2002; Lam and Selmer, 2004).
Walters and Auton-Cuff (2009) argue that due to disruption to their identity development during
childhood as a result of moving abroad, TCKs become used to adjusting and readjusting to new
environments. As such, they are used to adapting to new contexts and they often develop greater
sensitivity and tolerance towards the unknown (Selmer and Lam, 2004; Sheard, 2008; Lyttle et al.,
2011; Melles and Schwartz, 2013). By extension, Abe (2018) found that ATCKs show normative
changes in personality such as greater maturity and adjustment during adulthood. Those who
reported higher levels of multicultural engagement generally exhibited a more resilient personality
profile and more adaptive cognitive and affective styles. Hence, ATCKs, it is assumed, should find
it relatively easy to live and function in a new country (Gerner, Perry, Modelle and Archbold,
1992; Hayden, Rancic and Thompson, 2000).

A number of studies have found that a substantial feeling of accomplishment emerges from
the mastering of difficult encounters with host nationals (Bankston and Zhou, 1995; Portes and
Hao, 2002), which has been well-documented in the literature related to goal setting theory (Locke

http://mc.manuscriptcentral.com/ccsm
and Latham, 1990). The theory predicts that the outcomes will be higher if goals are challenging, yet attainable. Consequently, individuals’ efforts will be positively associated with the level of challenge in their goals – as long as it is within their reach. In other words, when confronted with a very difficult goal, the few individuals who take up the challenge and who are actually able to achieve it will be more dedicated (Selmer and Lauring, 2015). Gong and Chang (2007) found that expatriates who had set higher interaction adjustment goals were more likely to exert intense and persistent efforts than their counterparts with lower goals. When related to host country language acquisition, for example, which is closely linked to socio-cultural adjustment, expatriates that make the effort to learn a foreign language could be expected to feel greater personal development from the overall international experience (cf. Selmer and Lauring, 2015; Tenzer, Terjesen and Harzing, 2017; Lauring and Jonasson, 2018). We propose that ATCKs will experience more positive personal development compared to AMCKs, because it should be relatively easier for them to set (and achieve) higher and more challenging goals in the foreign culture, given they have attempted it in their adolescence. Moreover, by interacting more deeply with individuals from a foreign culture, we suggest ATCKs will experience higher levels of achievement and personal development. This leads to our second hypothesis:

**Hypothesis 2**

The relationship between interaction adjustment and experienced personal development is moderated by ATCK status, so that for ATCKs there will be a stronger association between interaction adjustment and personal development than for AMCKs.

**Method**

In this study, we targeted European business expatriates working in Asia, a region that is known to differ substantially in cultural and linguistic contexts from most European countries, which makes Asia especially challenging for expatriates (Shi and Franklin, 2013). The aim was to explore the moderating effect of ATCK vs AMCK status on the direct relationship between interaction adjustment and experienced personal development. Participants were obtained from a list of names and e-mail addresses acquired from embassies and other databases of white-collar foreign workers in Asia. Data were collected using an English language online survey. Responses came mainly from Singapore (23.32%), Indonesia (17.31%), Malaysia (12.72%), China (11.66 %) and Hong

http://mc.manuscriptcentral.com/ccsm
Kong (9.54%). Other host countries included Thailand, Philippines, Vietnam, India, Bangladesh, Lao and Pakistan. Expatriates originated from Sweden (13.07%), Denmark (13.07%), Norway (12.01%), Germany (10.25%) and the United Kingdom (8.83%). In total, 455 survey responses were received from an original database of 2007 potential participants (a 22.7 per cent response rate), from which a pool of 424 respondents was obtained after screening for incomplete surveys.

ATCK expatriates (n=86) had an average age of 48.3 years (SD=11.1), had spent 11.5 years in their host location (SD=9.6), 6.8 years in their current job (SD=6.0) and had worked abroad as an expatriate for 17.2 years (SD=10.5), including in their current job. The majority were male (83.7%), married (84.9%), and almost half had a master’s degree. AMCK expatriates (n=338) had an average age of 50.5 years (SD=11.0), had spent 9.9 years in their host location (SD=9.6), 6.7 years in their current job (SD=6.8), and had worked abroad as an expatriate for 15.2 years (SD=11.1), including in their current job. The majority were male (82.5%), married (81.4%) and 45 per cent had a master’s degree.

Interaction adjustment was gauged by a four-item, seven-point scale developed by Black and Stephens (1989). Response categories ranged from (1) “very unadjusted” to (4) “neutral” to (7) “completely adjusted”. A sample item is: “Interaction with host nationals outside of work” (alpha=.89). Experienced personal development was assessed by a self-developed four-item, seven-point scale ranging from (1) = “Strongly disagree” to (7) = “Strongly agree”, with a sample item: “During expatriation I have matured personally.” (alpha=.82) (see Appendix 1). To validate the two identified dimensions, a confirmatory factor analysis (CFA) of the full measurement model was conducted showing that all variables and indicators were distinct and appropriate for inclusion in the analysis (see Appendix 2).

As a moderator, ATCK/AMCK status was assessed by the question “As an adolescent (age 10-20), did you live in a foreign country for at least 6 months?” (e.g. Melles and Schwartz, 2013; Selmer and Lauring, 2014). In order to control for potential bias, five control variables were included in the analysis. Gender was assessed by the question: “Are you male or female?”. Time in current job in host location was estimated by a direct question to the respondents: “How long have you had your current job in the host location?”. Number of different jobs as an expatriate was gauged by the question: “How many different jobs as an expatriate have you had before your current job?”. Education was assessed by: “What is your educational level?”. Size of subsidiary was measured by a direct question: “How many employees work in your current workplace?”. In
Table 1, sample means, standard deviations and zero-order Pearson correlations are given for all variables.

Insert Table 1 about here

Results

Our two hypotheses were investigated using hierarchical multiple regression analysis with results in Table 2. Control variables were included in Step 1 resulting in significant relationships with three of the five control variables. Number of different jobs had a positive association with personal development ($\beta=.06; \ p<.01$), while Gender had a negative association with Personal development ($\beta=-.26; \ p<.05$). In Step 2, the interaction adjustment variable was added. Interaction adjustment had a positive association with Personal development ($\beta=.08; \ p<.05$). In Step 3, the moderator variable ATCK/AMCK was included (ATCK=1 and AMCK=0). The moderator variable was weakly and negatively associated with the criterion variable ($\beta=-.17; \ p<.10$). In Step 4, the interaction term was entered. Interaction adjustment x ATCK/AMCK was negatively associated with Personal development ($\beta=-.17; \ p<.05$). All $F$ values were statistically significant, indicating a proper fit between the regression model and the data.

Insert Table 2 about here

To explore the moderating relationships further, the significant interaction was plotted in Figure 1. For the ATCK group, Interaction adjustment had a weaker positive association with Personal development than for the AMCK group in the case of low interaction adjustment. However, as Figure 1 illustrates, Interaction adjustment has a much stronger effect on Personal development for ATCKs. Hence, both hypotheses of our study were supported.

Insert Figure 1 about here

Discussion

In this study, we have examined the relationship between interaction adjustment and experienced personal development among ATCKs and AMCKs. As predicted, our findings show a positive
association, which may be related to arguments that intercultural experience leads to personal development (Bankston and Zhou, 1995; Portes and Hao, 2002), but the effect of interaction adjustment varies. On the one hand, AMCKs experience personal development almost independently of their interaction adjustment with host nationals solely due to the novelty of the international experience. In contrast, while ATCKs experience less personal development when there is low interaction adjustment and more personal development when interaction adjustment increases, just being in the new country is not enough for them to feel they have developed personally; given their prior international experience as adolescents, they need to engage more deeply with the local population to experience personal development as the foreign setting in itself is not challenging enough. This finding could be explained by goal setting theory (Locke and Latham, 1990) predicting that relatively easy endeavors will not lead to much personal development.

Theoretical Implications

This research contributes to the literature on the relationship between adjustment and personal development and between international experience and adjustment, thus combining the two fields. In the first instance, the study supports the theoretical argument that adjustment leads to personal development (Haslberger et al., 2013), by empirically demonstrating a link between interaction adjustment and personal development. Second, prior studies (e.g., Takeuchi and Chen, 2013) have suggested there is a negative relationship between prior international experience and expatriate adjustment. In our research, while we have not focused on a direct effect of international experience but the moderating effect of having an early international experience indicated by ATCK status, we nonetheless find little direct effect of ATCK status. More interesting, however, is that early international experience in the form of ATCK status has an indirect effect influencing the relationship between interaction adjustment and personal development. In other words, the role of interaction adjustment changes for those with early international experience in that higher levels of interaction are required for ATCKs, than for AMCKs, to achieve a similar impact.

Our findings provide a more detailed picture of the relationship between international experience during adolescence and expatriate interaction adjustment. This should be considered in future attempts to build theory in the described line of enquiry. Future research might further explore if there are different effects of early vs late international experience. Similarly, the
distinction between AMCKs and ATCKs is an important one, because the point at which the individual experiences mobility for the first time (adolescence versus adulthood) could impact on the types of global work experiences they are likely to pursue (e.g., international business travel, commuting, short-term assignments, or long-term assignments). Bushong (2013) argues that it is not the geography of the ATCK experience, but the complex interplay of international experiences, that explains individuals’ behavior.

Other theories and concepts may also be useful to explore the link between international experience and adjustment. For example, social learning theory (Bandura, 1977) posits that individuals develop from interacting with people or observing their behavior. The social learning process can thus explain why ATCKs, in particular, acquire a desire for interaction adjustment at an early age arising from repeated exposure to, and mastery of, a variety of cultural settings.

The early acquisition of dynamic cross-cultural competencies by ATCKs (Tarique & Weisbord, 2013), which is similarly acquired through the social learning processes, can further explain why ATCKs potentially seek locally-embedded cultural experiences for personal development: working with HCNs can provide them the opportunity to hone and refine (‘put into practice’) their cross-cultural skills by testing out the behaviours that are likely to result in success in a particular cultural environment. Both are worthy of further research.

Lastly, further research is needed to determine which sets of shared experiences and characteristics of shared experiences among AMCKs are more likely to enhance their performance during expatriation compared to ATCKs. An understanding of outcomes from shared experiences across AMCKs and ATCKs can benefit in the talent management process. The integration of shared experiential learning with professional development can clarify and identify how expatriation facilitates or obstructs changes in an individual’s personal development (Kauffmann and Kuh, 1984; Hutchins, 1996); for example, to determine what the changes are in relation to the individual and whether these changes arise as a result of program design or a particular type of global work experience.

**Practical Implications**

We still know very little about ATCKs and about how expatriation during their adulthood develops them personally. Our study contributes to the growing literature linking global talent management to individuals’ personal characteristics (Caligiuri, Tarique and Jacobs, 2009; Tarique

http://mc.manuscriptcentral.com/ccsm
and Weisbord, 2013) by demonstrating differences in perceived personal development among ATCKs and AMCKs. This has implications in practice for the depth of contact expatriates should, or could, have with host nationals in the international work environment. For example, ATCKs may be the ‘preferred’ type of expatriate when the nature of the job abroad requires close contact (interaction) with HCNs to fulfill its purpose. As ATCKs’ personal development is closely linked to higher levels of HCN interaction, the likelihood of their success abroad increases when personal development correspondingly increases. Alternatively, when close contact with HCNs is not required, the talent pool can be widened to include AMCKs, with no perceived drawback.

A second implication is the location of the assignment. AMCKs appear to experience personal development solely due to the novelty of the international experience, thus where they are sent and/or work is less important than them actually going abroad. In contrast, ATCKs require significant HCN interaction to achieve similar levels of personal development, which is unlikely to be achieved by sending them, for example, as AEs to locations where the majority of colleagues will be other expatriates of the same or similar ethnicity. The same would apply for ATCKs employed locally as SIEs. ATCKs may thus be better suited to smaller subsidiaries in emerging economies where new businesses are needed to be established and which requires working closely with HCNs for expansion into local markets.

Third, personal development is enhanced for expatriates when appropriate learning experiences are made available to them (Caligiuri et al., 2009). AMCKs and ATCKs require development programs that are designed differently. Whereas AMCKs are likely to benefit from standard development programs available to all expatriates, ATCKs will require tailored programs that cater, for example, to technical competencies rather than cross-cultural competencies (that many already possess; Tarique & Weisbord, 2013). Moreover, Caligiuri (2006) argues that people will benefit in different ways from a developmental experience based on their individual aptitudes, such as knowledge, skills, abilities and other personal characteristics. Thus, offering the right developmental experience to ATCKs that is high on HCN interaction is likely to produce more effective performance, as a result of personal development, than offering them the same developmental experience as AMCKs.

Based on our study of ATCKs’ international experience and global talent management, three avenues of future research are proposed that can impact on practice. First, deeper understanding could be obtained by comparing intercultural exposure that is acquired in similar vs
very different cultures. Second, to avoid relying solely on self-referential data, future studies where colleagues are used as peer-raters are encouraged and where intercultural performance is more objectively assessed comparing ATCKs and AMCKs in the workplace. Lastly, as research has argued that personal development can vary between different types of expatriates (AEs vs. SIEs) (e.g. Doherty et al., 2011; Guttmansen, Francesco and Chapman, 2018; Lauring and Selmer, 2018), future studies could explore the varying roles of ATCK status in relation to adjustment and personal development for each type. For example, ATCKs are likely to constitute a higher proportion of SIEs, given their preference for independence and a free-agent career model (Trabka, 2015), which arises (one would assume) from an early life of necessary adaptability (Selmer et al., forthcoming). Applying AE-specific approaches to their adjustment and personal development is unlikely to be adequate given the differences in competencies and motivation for each.

Limitations

As in all studies, ours has several shortcomings that limits generalizability. Cross-sectional self-reports, for example, may have created common method variance (CMV). However, we took a number of measures such as preventing respondents to go back to previous pages of the survey, and assuring confidentiality (Podsakoff, MacKenzie, Lee and Podsakoff, 2003). Most importantly it has been argued that moderation effects also cannot be caused by CMV (Chang, van Witteloostuijn and Eden, 2010). As our main finding relates to the moderating effect of ATCK vs. AMCKs, it could be argued that CMV is not a serious problem.

The control variable used to classify the respondents as either ATCK vs AMCK could be questioned, given we set the minimum time requirement at 6 months for ATCK status and used only a single item. While noting that studies outside expatriation have used time requirements of one year (Useem, 1976), two years (Hoersting and Jenkins, 2011) and even three years (Lytte et al., 2011; Moore and Barker, 2012), we relied on the 6-month single item measure used in other expatriate studies (Selmer and Lauring, 2014; Melles and Schwartz, 2012) to justify the time requirement. Had we used a longer time requirement, the sample size of ATCKs may have been smaller, making a comparison between ATCKs and AMCKs more difficult. The fact that we actually did find an effect of ATCK status at just 6 months indicates that even a short time in a foreign culture during adolescence is potentially sufficient for altering adjustment patterns. Our findings thus support the use of the 6-month measure. Another issue is that culture has been argued
to been more complex and dynamic than what can be assessed from nation state boundaries (Lauring, Bjerregaard and Klimmøller, 2018). The discussion about cultural dynamics in relation to ATCKs should be further included in future research.

We only used interaction adjustment for this study as we see this as the most theoretically relevant. While we also conducted analyses of job adjustment and general adjustment, there was no moderation effect found in relation to ATCK status; we have thus not included the analysis in this article. However, future studies could explore the relationship between other dimensions of adjustment, personal development and early international experience.

Appendix 2.

In order to evaluate model fit, five different goodness-of-fit indices were used: The $\chi^2$-test was performed against the saturated model with $p \geq 0.05$ demonstrating a good model fit. The root mean square error of approximation (RMSEA) and standardized root mean square residual (SRMR) were considered to indicate good model fit with values less than 0.06 and 0.08, respectively. Additionally, the comparative fit index (CFI) and the Tucker-Lewis index (TLI) were assessed with values above or close to 0.95 indicating good model fit (Hu and Bentler, 1999).

Initially, a CFA on the full model was performed. Apart from the $\chi^2$-test ($\chi^2(19) = 89.773$, $p = 0.000$), all of the fit-indicators indicated a good model fit of the latent variable construct (RMSEA=0.097; SRMR=0.036; CFI = 0.964; TLI = 0.933). As the $\chi^2$- test suffers from several drawbacks, e.g. sample size sensitivity (Hay and Bechger, 2007), the model was considered to fit the data well. Moreover, in the measurement model, all standardized loadings were considerably (with the smallest being 0.55) and highly statistically significant. I.e. both latent factors explained the observed indicators with large statistical significance. Moreover, since the factor correlation was 0.18, discriminant validity was demonstrated in the full measurement model. To validate the measurement model further, the full measurement model was compared to a nested model with only one factor. As illustrated in Table 1, results of the goodness-of-fit indices and $\chi^2$- difference test revealed that the full measurement model displayed significantly better fit than the nested measurement model. Based on this, all variables and indicators were distinct and appropriate for inclusion in the analysis.
